

Additional Note

We have recently detected a bug in the code used to derive the income variables at age 11 (Wave 5), derived from the questions on banded net income. The variable names affected are: EOEDE000, EOEDP000, EOECDUK0, and EOECDSC0. We have debugged the code and redeposited these amended variables on July 2017 and they are now available for download via the UK Data Archive.

The nature of the error means that the absolute values of income were overestimated, even though the ranking of households in terms of their 'OECD'-equivalised weekly income has remained largely the same.

The binary poverty indicator was constructed based on the OECD-equivalised income and the national distribution published in HBAI statistics, for consistency with previous sweeps. The indicator takes the value of one if the OECD equivalised income of the household is below 60% of the DWP national HBAI weekly median income, which was equal to £256 in 2011-12. The poverty rate based on the revised variable is 4 percentage points higher than that based on the originally deposited variable.

If you require further information please contact clsfeedback@ioe.ac.uk

Our team of researchers and methodologists is also working to provide some additional information which refines further the measures of family income.

Prof. Emla Fitzsimons, July 2017

Principal Investigator of the Millennium Cohort Study
